In contrast to previous studies that have demonstrated clear effects of biodiversity on ecosystem function under largely homogeneous conditions (e.g. [52–55]), our analyses demonstrate that species effects on ecosystem process (net movement and bioturbation intensity) and function (nutrient concentration) are non-additive, species-specific and mediated by habitat structure.

[Habitat structure mediates biodiversity effects on ...](#)

habitat patches can enhance biodiversity effects on eco-system functioning and community stability because environmental heterogeneity promotes niche diversity [28,29]. Dispersal between resource patches, however, may also lessen variability in grazer abundance and reduce diversity effects on primary production [30].

Habitat Structure Mediates Biodiversity Effects On

However, spatial structure has been shown to affect species coexistence and habitat deterioration is one of the biggest threats to biodiversity. We therefore explore a spatially explicit two-species model and assess the effects of habitat structure on species coexistence using a wide diversity of fractal landscapes.
