Numerical Solution Of Ill Posed Cauchy

Numerical Methods for the Solution of Ill-Posed Problems We consider the solution of ill-conditioned linear systems using the singular value decomposition, and show how this can improve the accuracy of the computed solution for certain kinds of right-hand sides. Then we indicate how this technique is especially appropriate for some classical ill-posed problems of mathematical physics.

On the Numerical Solution of Ill-Conditioned Linear ... Many problems in science, technology and engineering are posed in the form of operator equations of the first kind, with the operator and RHS approximately known. But such problems often turn out to be ill-posed, having no solution, or a non-unique solution, and/or an unstable solution.

Ill-posed problems - Encyclopedia of Mathematics One simple example of an ill-posed problem is given by the equation $y_{\parallel} = (3/2)y_{\perp} 1/3$ with $y_{\parallel}(0) = 0$. Since the solution is not unique (it could be plus t 3/2). As this violates rule 2 of the Hadamard criteria, the problem is ill posed.

Improperly Posed Problems and Their Numerical Treatment The formal solution is written as a hyperbolic cosine function in terms of a parabolic unbounded operator. The ill-posedness is dealt with by truncating the large eigenvalues of the operator. The approximate solution is computed by projecting onto a smaller subspace generated by the Arnoldi algorithm applied on the inverse of the operator.

An approach has been worked out to solve ill-posed problems that makes it possible to construct numerical methods that approximate solutions of essentially ill-posed problems of the form \ref {eq1} which are stable under small changes of the data. In this context, both the right-hand side \$u\$ and the operator \$A\$ should be among the data.

Abstract Many numerical methods for the solution of linear ill-posed problems apply Tikhonov regularization. This paper presents a new numerical method, based on Lanczos bidiagonalization and Gauss quadrature, for Tikhonov regularization of large-scale problems. An estimate of the norm of the error in the data is assumed to be available.

If the problem is well-posed, then it stands a good chance of solution on a computer using a stable algorithm. If it is not well-posed, it needs to be re-formulated for numerical treatment. Typically this involves including additional assumptions, such as smoothness of solution. This process is known as regularization. Tikhonov regularization is one of the most commonly used for regularization of linear ill-posed problems.

In this work, we analyze the regularizing property of the stochastic gradient descent for the numerical solution of a class of nonlinear system to obtain an unbiased stochastic estimate of the gradient and then performs a descent step with the estimated gradient.
