Phase change materials (PCMs) are substances which absorb or release large amounts of so-called “latent” heat when they go through a change in their physical state, i.e., from solid to liquid and vice versa. In a heating or a cooling process, this phase change takes place as soon as the material reaches its specific phase change temperature.

Phase Change Materials: Science and Applications provides a comprehensive overview of the properties that characterize phase change materials from theoretical and experimental perspectives, with a focus on emerging technological applications. An informative introductory chapter provides the history of phase change memories, including the discovery, early systems and advances over time.

Phase change material. Phase change material (PCM) such as paraffin can be incorporated into textile materials through spinning dope, and mixing it into the insulating foams or coating, so providing a thermal regulating function. When the environmental temperature reaches the PCM melting point, the physical state of PCM in the fabric will change from solid to liquid, resulting in the absorption of heat; heat is released when the temperature reaches the freezing point of the PCM.

2. Phase change materials 2.1. Classification of PCMs. PCMs can be classified in many ways, such as composition of materials , energy storage methods , thermal storage temperature , phase , etc. According to the composition of materials, PCMs are commonly divided into: inorganic PCMs, organic PCMs and composite PCMs .Inorganic PCMs can be furtherly divided into salt hydrates, inorganic ...

Phase change materials (PCMs) store thermal energy via the latent heat of phase transitions. PCMs can be used to provide district cooling (subambient transition temperatures), to buffer thermal swings in buildings (near ambient transition temperatures), and to store solar thermal energy for short-term or seasonal applications (higher transition temperatures).

Latent heat storage materials or phase change materials, PCMs, change its phase during the energy storage process. In general, latent heat storage is greater than the sensible heat storage, and therefore less mass and volume of the material is required to obtain a good energy efficiency, in addition, the phase change happens at a constant temperature, thus avoiding inconveniences of corrosion ...

Abstract. Polyurethane (PU) based phase change materials (PCMs) undergo the solid–solid phase transition and offer state-of-the-art thermal energy storage (TES). Nevertheless, the exploration of these PCMs in real-life applicable smart devices is generally hindered by the technical bottleneck of structural rigidity, low thermal storage capacity and lack of

functionalities.

Phase change materials (PCMs) based thermal energy storage (TES) has proved to have great potential in various energy-related applications. The high energy storage density enables TES to eliminate the imbalance between energy supply and demand. With the fast-rising demand for cold energy, cold thermal energy storage is becoming very appealing.

Second, BN phase change composite films, made by dipping BN aerogel films into the melts of the organic phase change materials (e.g., paraffin), can effectively cool the portable electronics as the organic phase change materials filled in the aerogel matrix can serve as a smart thermal-regulator to absorb the undesired heat via solid–liquid phase transition. These two typical strategies of the flexible BN aerogel film-directed thermal management could assist in efforts to miniaturize ...
